The Pharmaceutical Benefits Scheme (PBS) is the Australian government drugs subsidy scheme.

- Many drugs bought from pharmacies are subsidised to allow more equitable access to modern drugs.
- The cost to government is determined by the number and types of drugs purchased. Currently nearly 1% of GDP.
- The total cost is budgeted based on forecasts of drug usage.

- In 2001: \$4.5 billion budget, under-forecasted by \$800 million.
- Thousands of products. Seasonal demand.
- Subject to covert marketing, volatile products, uncontrollable expenditure.
- Although monthly data available for 10 years, data are aggregated to annual values, and only the first three years are used in estimating the forecasts.
- All forecasts being done with the FORECAST function in MS-Excel!

Historical perspective

- Developed in the 1950s and 1960s as methods (algorithms) to produce point forecasts.
- Combine a "level", "trend" (slope) and "seasonal" component to describe a time series.
- The rate of change of the components are controlled by "smoothing parameters": α , β and γ respectively.
- Need to choose best values for the smoothing parameters (and initial states).
- Equivalent ETS state space models developed in the 1990s and 2000s.

We want a model that captures the level (ℓ_t) , trend (b_t) and seasonality (s_t) .

How do we combine these elements?

We want a model that captures the level (ℓ_t) , trend (b_t) and seasonality (s_t) .

How do we combine these elements?

Additively?

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

We want a model that captures the level (ℓ_t) , trend (b_t) and seasonality (s_t) .

How do we combine these elements?

Additively?

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

Multiplicatively?

$$y_t = \ell_{t-1}b_{t-1}s_{t-m}(1+\varepsilon_t)$$

We want a model that captures the level (ℓ_t) , trend (b_t) and seasonality (s_t) .

How do we combine these elements?

Additively?

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

Multiplicatively?

$$y_t = \ell_{t-1}b_{t-1}s_{t-m}(1+\varepsilon_t)$$

Perhaps a mix of both?

$$y_t = (\ell_{t-1} + b_{t-1})s_{t-m} + \varepsilon_t$$

We want a model that captures the level (ℓ_t) , trend (b_t) and seasonality (s_t) .

How do we combine these elements?

Additively?

 $y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$

Multiplicatively?

 $y_t = \ell_{t-1}b_{t-1}s_{t-m}(1 + \varepsilon_t)$

Perhaps a mix of both?

 $y_t = (\ell_{t-1} + b_{t-1})s_{t-m} + \varepsilon_t$

How do the level, trend and seasonal components evolve over time?

ETS models

General notation ETS: ExponenTial Smoothing

Error Trend Season

Error: Additive ("A") or multiplicative ("M")

ETS models

```

→ ↑ 

Error Trend Season
```

Error: Additive ("A") or multiplicative ("M")

Trend: None ("N"), additive ("A"), multiplicative ("M"), or damped ("Ad" or "Md").

ETS models

```
General notation ETS: ExponenTial Smoothing

Error Trend Season
```

Error: Additive ("A") or multiplicative ("M")

Trend: None ("N"), additive ("A"), multiplicative ("M"), or damped ("Ad" or "Md").

Seasonality: None ("N"), additive ("A") or multiplicative ("M")

ETS(A,N,N): SES with additive errors

Forecast equation
$$\hat{y}_{T+h|T} = \ell_T$$

Measurement equation $y_t = \ell_{t-1} + \varepsilon_t$

State equation $\ell_t = \ell_{t-1} + \alpha \varepsilon_t$

where $\varepsilon_t \sim \text{NID}(0, \sigma^2)$.

ETS(A,N,N): SES with additive errors

Forecast equation
$$\hat{y}_{T+h|T} = \ell_T$$

Measurement equation $y_t = \ell_{t-1} + \varepsilon_t$

State equation $\ell_t = \ell_{t-1} + \alpha \varepsilon_t$

where $\varepsilon_t \sim \text{NID}(0, \sigma^2)$.

- "innovations" or "single source of error" because equations have the same error process, ε_t .
- Measurement equation: relationship between observations and states.
- Transition/state equation(s): evolution of state(s) over time.

ETS(M,N,N): SES with multiplicative errors

$$\hat{y}_{T+h|T} = \ell_T$$

$$y_t = \ell_{t-1}(1 + \varepsilon_t)$$

$$\ell_t = \ell_{t-1}(1 + \alpha \varepsilon_t)$$

where $\varepsilon_t \sim \text{NID}(0, \sigma^2)$.

ETS(M,N,N): SES with multiplicative errors

Forecast equation
$$\hat{y}_{T+h|T} = \ell_T$$

Measurement equation $y_t = \ell_{t-1}(1 + \varepsilon_t)$

State equation $\ell_t = \ell_{t-1}(1 + \alpha \varepsilon_t)$

where $\varepsilon_t \sim \text{NID}(0, \sigma^2)$.

Models with additive and multiplicative errors with the same parameters generate the same point forecasts but different prediction intervals.

ETS(A,Ad,N): Damped trend method

Additive errors

Forecast equation Measurement equation State equations

$$\hat{y}_{T+h|T} = \ell_T + (\phi + \dots + \phi^{h-1})b_T$$

$$y_t = (\ell_{t-1} + \phi b_{t-1}) + \varepsilon_t$$

$$\ell_t = (\ell_{t-1} + \phi b_{t-1}) + \alpha \varepsilon_t$$

$$b_t = \phi b_{t-1} + \beta \varepsilon_t$$

ETS(A,Ad,N): Damped trend method

Additive errors

Forecast equation Measurement equation State equations

$$\hat{y}_{T+h|T} = \ell_T + (\phi + \dots + \phi^{h-1})b_T$$

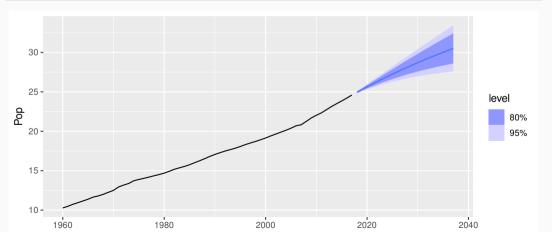

$$y_t = (\ell_{t-1} + \phi b_{t-1}) + \varepsilon_t$$

$$\ell_t = (\ell_{t-1} + \phi b_{t-1}) + \alpha \varepsilon_t$$

$$b_t = \phi b_{t-1} + \beta \varepsilon_t$$

- Damping parameter $0 < \phi < 1$.
- If ϕ = 1, identical to Holt's linear trend.
- As $h \to \infty$, $\hat{y}_{T+h|T} \to \ell_T + \phi b_T/(1-\phi)$.
- Short-run forecasts trended, long-run forecasts constant.

- 6 Lab Session 15
- 7 Non-Gaussian forecast distributions

Lab Session 14

Try forecasting the Australian GDP from the global_economy data set using an ETS model.

Experiment with the various options in the ETS() function to see how much the forecasts change with damped trend, or with a Box-Cox transformation. Try to develop an intuition of what each is doing to the forecasts.

[Hint: use h=20 when forecasting, so you can clearly see the differences between the various options when plotting the forecasts.]

ETS(A,A,A): Holt-Winters additive method

Forecast equation
Observation equation
State equations

$$\hat{y}_{t+h|t} = \ell_t + hb_t + s_{t+h-m(k+1)}$$

$$y_t = \ell_{t-1} + b_{t-1} + s_{t-m} + \varepsilon_t$$

$$\ell_t = \ell_{t-1} + b_{t-1} + \alpha \varepsilon_t$$

$$b_t = b_{t-1} + \beta \varepsilon_t$$

$$s_t = s_{t-m} + \gamma \varepsilon_t$$

- \blacksquare k = integer part of (h-1)/m.
- \square $\sum_i s_i \approx 0.$
- Parameters: $0 \le \alpha \le 1$, $0 \le \beta^* \le 1$, $0 \le \gamma \le 1 \alpha$ and m = period of seasonality (e.g. m = 4 for quarterly data).

ETS(M,A,M): Holt-Winters multiplicative method

Forecast equation
$$\hat{y}_{t+h|t} = (\ell_t + hb_t)s_{t+h-m(k+1)}$$
Observation equation $y_t = (\ell_{t-1} + b_{t-1})s_{t-m}(1 + \varepsilon_t)$
State equations $\ell_t = (\ell_{t-1} + b_{t-1})(1 + \alpha \varepsilon_t)$
 $b_t = b_{t-1}(1 + \beta \varepsilon_t)$
 $s_t = s_{t-m}(1 + \gamma \varepsilon_t)$
 k is integer part of $(h-1)/m$.

- $\sum_{i} s_{i} \approx m$.
- Parameters: $0 \le \alpha \le 1$, $0 \le \beta^* \le 1$, $0 \le \gamma \le 1 \alpha$ and m = period of seasonality (e.g. m = 4 for quarterly data).

Exponential smoothing models

| Additive Error | | Seasonal Component | | | |
|-----------------------|-------------------|---------------------|------------|-------------------------------------------|--|
| Trend | | N | Α | M | |
| | Component | (None) | (Additive) | (Multiplicative) | |
| N | (None) | A,N,N | A,N,A | <u> </u> | |
| Α | (Additive) | A,A,N | A,A,A | $\Delta_{\downarrow}\Delta_{\downarrow}M$ | |
| A_d | (Additive damped) | A,A _d ,N | A,A_d,A | ۸,۸۵,۸ ۸ | |

| Multiplicative Error | | Seasonal Component | | | |
|----------------------|-------------------|---------------------|------------|---------------------|--|
| | Trend | N | Α | M | |
| | Component | (None) | (Additive) | (Multiplicative) | |
| N | (None) | M,N,N | M,N,A | M,N,M | |
| Α | (Additive) | M,A,N | M,A,A | M,A,M | |
| A_{d} | (Additive damped) | M,A _d ,N | M,A_d,A | M,A _d ,M | |

Estimating ETS models

- Smoothing parameters α , β , γ and ϕ , and the initial states ℓ_0 , b_0 , s_0 , s_{-1} , ..., s_{-m+1} are estimated by maximising the "likelihood" = the probability of the data arising from the specified model.
- For models with additive errors equivalent to minimising SSE.
- For models with multiplicative errors, **not** equivalent to minimising SSE.

Model selection

Akaike's Information Criterion

$$AIC = -2\log(L) + 2k$$

where L is the likelihood and k is the number of parameters & initial states estimated in the model.

Model selection

Akaike's Information Criterion

$$AIC = -2 \log(L) + 2k$$

where L is the likelihood and k is the number of parameters & initial states estimated in the model.

Corrected AIC

$$AIC_c = AIC + \frac{2k(k+1)}{T - k - 1}$$

which is the AIC corrected (for small sample bias).

Model selection

Akaike's Information Criterion

$$AIC = -2\log(L) + 2k$$

where *L* is the likelihood and *k* is the number of parameters & initial states estimated in the model.

Corrected AIC

$$AIC_c = AIC + \frac{2k(k+1)}{T - k - 1}$$

which is the AIC corrected (for small sample bias).

Bayesian Information Criterion

$$BIC = AIC + k(\log(T) - 2).$$

AIC and cross-validation

Minimizing the AIC assuming Gaussian residuals is asymptotically equivalent to minimizing one-step time series cross validation MSE.

Automatic forecasting

From Hyndman et al. (IJF, 2002):

- Apply each model that is appropriate to the data.

 Optimize parameters and initial values using MLE.
- Select best method using AICc.
- Produce forecasts using best method.
- Obtain forecast intervals using underlying state space model.
 - Method performed very well in M3 competition.
- Used as a benchmark in the M4 competition.

- 1 Exponential smoothing
- 2 Trend methods
- 3 Lab Session 14
- 4 Seasonal methods
- 5 ETS taxonomy
- 6 Lab Session 15
- 7 Non-Gaussian forecast distributions

Lab Session 15

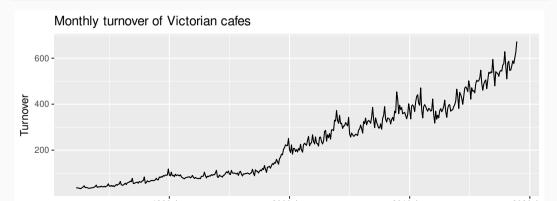

Find an ETS model for the Gas data from aus_production.

- Why is multiplicative seasonality necessary here?
- Experiment with making the trend damped. Does it improve the forecasts?

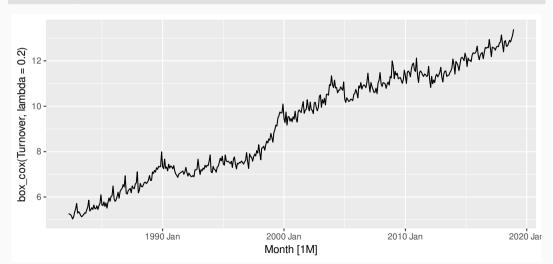

Outline

- 1 Exponential smoothing
- 2 Trend methods
